Bonn, September 2019
Version 4.0
This edition updates the versions published in 2018 and implements a methodical harmonisation of the time series 2002 – 2008 – 2017. A component of this is also an adjustment of the weighting and extrapolation to accommodate the census-related corrections of the population figures for 2002 and 2008.

Mobility in Germany 2017 – what's it about?

Travelling and mobility influence our day-to-day lives. They are a part of our social lives, to different degrees, during work and education, leisure activities and everyday personal business. Precise knowledge about these mobility requirements and everyday transport occurrences is a prerequisite to providing the required resources. While a constantly increasing growth in car mobility in recent decades was recorded, much effort now concentrates on once more promoting awareness of other transport services, such as public transport, cycling and walking. It is apparent, not only in Germany, that the continuous growth of car transport is reaching its limits. Despite this, it remains a formative component of transport and must be actively modelled.

But where are we at on this path? How do the citizens of Germany make use of the transport services? How has this changed in recent years? What about people with reduced mobility? Do we all have similar mobility habits or are there any differences?

These and other questions are looked at in detail by the Mobility in Germany (MiD) study. This report presents an overview of the core results for 2017. In addition to the extensive findings report of 2017 as well as an own time-series report, it is intended to provide insights into the most important benchmarks and relationships.

Further documentation has been written in addition to these short and also long reports. These are available at www.mobilitaet-in-deutschland.de. All documentation on the earlier surveys by Mobility in Germany in the years 2002 and 2008 are also available there (only in German). Additional information on these and a list of all regional Mobility in Germany 2017 clients can be found at the end of this short report.

We hope you enjoy reading!

Your Mobility in Germany project team

Data base

After 2002 and 2008, the Federal Ministry of Transport and Digital Infrastructure commissioned the infas Institute for Applied Social Sciences to carry out the Mobility in Germany study for the third time in 2017. Involved on the part of the client were over 60 regional partners who had commissioned additional regional samples. As previously in 2008, processing was carried out together with the Institute of Transport Research at the German Aerospace Centre. In addition, the project team was extended to include IVT Research as well as infas 360.

The field phase of the current survey, with a reference survey date stretching for over twelve months, took place in the period between May 2016 and September 2017. The study participants were able to take part in a multistage procedure in writing, by telephone or online. Within the realised overall sample of 156,420 households, 33,389 households were allotted to the base sample for the whole of Germany and 123,031 to the additional regional samples. A total of 316,361 persons were interviewed who reported on 960,619 trips on their respective survey dates. The precise contents are documented in an overview at the end of this report.

The evaluation of the base sample as well as the regional additions are integrated. The extrapolation of the results provides extensive key values for the year 2017 on day-to-day mobility among Germany's residential population and refers to all the trips they made within Germany.

With this edition of the short report, a direct comparison with the earlier surveys of 2002 and 2008 is possible. This is guaranteed by the retrospective regionalised adjustment of the extrapolations to incorporate the census correction of the population figures carried out in 2011 as well as further methodological adjustments for 2002 and 2008 to the approach in 2017.

Results telegram

Overall transport volume virtually stable, but regionally very different

– Seen as a whole, the total German passenger-transport volume (measured as number of trips) and as well the total passenger-kilometre performance (measured as the passenger kilometres travelled) in total have changed only a little compared to the last Mobility in Germany surveys from 2002 and 2008. The volume has reduced slightly compared to 2008 and now lies at almost 260 mio. trips per day. On the other hand, the transport distance has slightly increased to around 3.2 bn. passenger kilometres a day.

– This overall development is misleading in terms of regional differences. In particular in the major towns, both values increase significantly in some cases, not least because of the population growth there – with corresponding transport burdens in the conurbation areas on the one hand and benefits for public transport on the other.

– The so-called 'rate of mobility', which means the share of trip makers, has declined. While in 2008 an average of 90 per cent of the citizens were on the move on an average day, this value achieved only 85 per cent in 2017. This leads to a somewhat reduced average number of 3.1 trips per person and day. In 2008 the respective value was 3.4 trips. The above average decline for children and young people is striking as well as for households with lower economic status.

Still low growth in the proportion of cars

– The transport modal split, measured as share of mode of transport of all trips, shows a slight growth in private motorised transport and low proportional increases for the remaining modes of transport. The bicycle, bus and rail are among the winners, in particular in urban areas. On the other hand, the proportional value of trips covered on foot alone is declining in towns and the country. In Mobility in Germany, a 'trip' is understood to be a movement from origin to destination including possible stops and changes in modes of transport.

– The modal split across the whole of Germany in 2017 thus lies at 22 per cent for trips covered on foot alone, 11 per cent for the bicycle, 43 per cent for trips by the car driver as well as 14 per cent for those by the car passenger. Public transport including long-distance transport reached a proportion of 10 per cent of the transport volume. In this examination of the 'Main travel mode', trips for which different modes of transport were used are summarised according to a hierarchy and allocated to one of the above-mentioned modes of transport.

– The examination of passenger-kilometre performance, i.e. the covered passenger kilometres, shows a clear increase for the bicycle as well as public transport. The vehicle mileage of car drivers has increased to a lesser extent. The values for the car passengers have declined somewhat.

Plus for the environmental alliance of bicycle, bus and rail, but minus for pedestrian traffic

– The bicycle is on the rise, especially in the kilometres cycled. Thus, the bicycle is being ridden in particular for somewhat further distances. In total, the cycled passenger kilometres compared to 2002 have increased by around a quarter. Compared to 2008 this is more than a tenth.

– Public transport has grown proportionally and absolutely in volume, but in particular in kilometre performance. Here it has increased by a half compared to 2002 and by a tenth compared to 2008.

– It's a different picture when it comes to pedestrian traffic: this has made losses, in particular in modal share of transport volume, and went down from 25 per cent in 2008 to 22 per cent in the year 2017.

– Even though local public transport has increased and has benefited from growing commuter transport it is the mode of transport with the comparably most unfavourable subjective assessment by the interviewees. In addition, it is the least gladly used. The favourite on both counts is the car.

More and bigger cars

– The fleet of cars has now grown to a good 43 mio. vehicles in private households. Unlike in 2008, there is therefore now more than one car to each household. The fleet size has particularly grown in the eastern German states and rural regions. Outside the towns, 90 per cent of households now have at least one car at their disposal. When looking at Germany as a whole, 23 per cent of households continue to be without a car. However, households with more than one car have recorded a slight rise.

– Within the fleet, SUVs, off-road vehicles and vans have doubled their proportion in the surveyed households compared to 2008 from around ten to now around 20 per cent.

– The average occupancy rate of cars has hardly changed. It lies at around 1.5 persons for both 2002 and 2008.

– Overall, possession of a car driving licence has increased slightly. In 2017, 87 per cent of 17 year-olds and older have a car driving licence – one per cent more than in 2008. As always, a differentiated view is required here too. The proportion declines, particularly in the age-group of under 30 year-olds. In the case of senior citizens however, it has now exceeded the 80 per cent mark.

Less activity among children, continued growth in car preference among senior citizens

– Young adults in major towns are less car-orientated than their peers were in previous years. This can also be seen in the declining quotas of driving licence possession. It's a different picture among the older age groups. For example the day-to-day mobility of 30-60 year-olds is only slightly different to that of this age group in the Mobility in Germany surveys of 2002 and 2008.

– The level of mobility among children and young people has changed. They are less on the move than the same age groups in 2002 and 2008. However, this differs according to household situation and economic status.

– As was the case between 2002 and 2008, automobility among senior citizens grew quite significantly, in particular in the older age groups. The background to this is primarily more older women who are sitting at the wheel themselves and more often have a car at their disposal than previous female senior citizens.

– Car sharing organisations are finding their members in the major towns where more than every tenth household already has at least one membership. However, the actual utilisation does not keep the same pace. Four out of ten car sharers almost never make use of the service. Even the remaining car sharing customers only use these vehicles mainly sporadically. Shared cars are therefore most likely to represent an occasional option with low proportion of vehicle mileage.

Beginnings of a transport turnaround are visible but not nearly completed

– The frequently discussed transport turnaround is only recognisable in urban areas, but even there, is not yet achieving the desired overall dynamic. Overall and primarily outside the towns the car remains by far the number one mode of transport, in particular when looking at passenger kilometres. In addition, changes are currently being driven, sometimes more through structural effects such as (re-) urbanisation and the growth in employment than through transport improvements.

– The developments to be ascertained in terms of a somewhat reduced rate of mobility and the number of day-to-day trips can also be identified in a similar form in the current national mobility surveys in Great Britain and the USA. This suggests, despite all differences, parallel developments in the western industrial societies.

– However, under the surface of average values for events in passenger transport, different and sometimes opposing developments can be recorded. These run along the age limits and show so-called 'cohort effects'. While day-to-day mobility is no longer so clearly influenced by the car in particular among the younger generations, its importance among the older generations is growing. A further divide runs between town and country, also with a more diverse mobility in the towns and a continuously growing automobility in the rural areas. A third complex comprises aspects of social participation. Thus, the level of mobility reduces in economically weak households while it stays the same at the other end of this scale or even goes against the trend in some segments.

How often, how far and how long are we on the move?

Share of trip-makers

On average during the course of a year, 85 per cent of citizens are out of the house on any one randomly selected day. This value is somewhat higher at 88 per cent on working days, lies at 82 per cent on Saturdays and at 73 per cent on Sundays. These values have fallen slightly compared to the last survey in the year 2008. At that point in time they lay at an overall 90 per cent compared to 87 per cent on Saturdays and 82 per cent on Sundays. Thus, the declines are greater at the weekends than on working days. A lower rate of mobility is decisive for these changes, above all among children and young people and in households which lie in the lower groups from an economic point of view.

3.1 trips and 85 minutes a day

These activity quotas lead to an average daily number of 3.1 trips which each of us cover. This value has also fallen somewhat compared to the result of 3.4 in the year 2008. In comparison, the distance covered each day has risen slightly. This lay at 39 kilometres in 2017. In 2008 it amounted to 38 kilometres and 33 kilometres in 2002. Accompanying this is a slight rise in day-to-day time on the move. In 2002 this lay at just below the 80 minute limit, and now amounts to 85 minutes – each including commercial transport.

Daily transport volume and travelled kilometres

When extrapolated, these values lead to a daily transport volume of almost 260 mio. trips and 3.2 bn. passenger kilometres. The volume declined slightly in 2017, however the distance travelled rose slightly. We are thus covering less trips on average per day. However, these are on average somewhat longer and take up more time than they did several years ago. In order to be able to reliably compare the current extrapolated values with the results of the surveys from 2002 and 2008, the values for 2002 and 2008 were newly determined according to the census correction which has been available since 2011. Likewise, plausibility checks developed in Mobility in Germany 2017 were applied in the trip evaluation in order to ensure the direct comparability of all three points in time.

The correction necessitated by the earlier census leads to somewhat lower population figures for both points in time than were taken as basis at that time, particularly in the larger towns. Therefore, for both 2002 as well as 2008, this results in an overall population of almost 81 mio. This rises to almost 83 mio. citizens in 2017.

As will be demonstrated in one of the following chapters of this short report, there are differences in these key mobility values over the whole of Germany and, above all, in their development within the individual population groups. But also when considered from a regional perspective, the trends in the extrapolated results on volume and performance are not the same. Population growth, in particular in the very large towns and their conurbation areas, lead, when considered absolutely, to an increase in transport demand and thus also to a greater utilisation of the existing infrastructure which does not usually grow to the same extent. The transport demand situation is more relaxed away from the conurbation areas.

In order to demonstrate this differentiation, the Mobility in Germany figures for this report are differentiated according to seven area categories of a consolidated regional statistical spatial type. This is a building block of the new spatial typology (RegioStaR) by BMVI. The results for the daily transport volume as well as the transport distance and other selected core parameters on the three points in time 2002, 2008 and 2017 are presented in the table on the right-hand side.

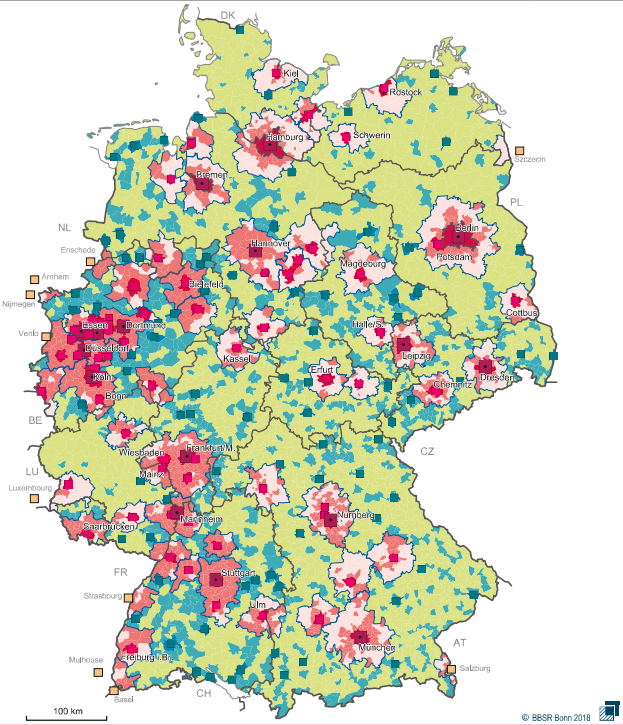

Notes on the updated time comparison

It is intended that Mobility in Germany 2017 should also enable a time comparison with the earlier surveys from 2002 and 2008. To this end, further developments in the data plausibility checks as well as the weighting carried out in 2017 were transferred to the 2002 and 2008 data bases. In addition, the extrapolation which was newly generated for these two points in time now take into account the census correction of the population figures which was carried out in 2011 on a smaller-scale level (municipalities). Detailed depictions of the working steps carried out with this data harmonisation are included in the time-series report which is available separately.

General key values and transport volume according to regional statistical spatial type (RegioStaR7)

	2002	2008	2017

Rural region – small-town area, village area	*416*	*669*	**569**	*in mio.*

*At the end of the year 2015 (regional differentiation of this evaluation is only available for this point in time), in 2017 already approx. 82.7 mio. according to Destatis
Absolute values for 2002 and 2008 recalculated according to a smaller scale (on a municipality level), census-related correction of the population figures

Consolidated regional statistical spatial type (RegioStaR 7)

The regional statistical spatial type (RegioStaR 7) displayed on the map was developed by the Federal Ministry of Transport and Digital Infrastructure and the Federal Institute for Research on Building, Urban Affairs and Spatial Development. This typification was only developed in 2018 and was not a part of the sample concept in any of the three Mobility in Germany surveys. The interviewees' municipalities of residence were retrospectively allocated to a RegioStaR type for the years 2002 and 2008. While the development of average values and relative shares can be depicted relatively well in this way, values extrapolated to absolute figures provide only an approximate orientation and are therefore to be interpreted with caution. These values are therefore shown in italics in the table.

Urban regions

- Metropolis
- Regiopolis and large city
- Medium-sized city, urban area

What about access to car, bicycle, bus and rail as well as pedestrian traffic?

More than one car per household

The number of private households in 2017 lay at around 41 mio. In 2002 around two mio. households less were recorded. In 2008 the number was around 40 mio. The number of households is rising. At the same time the average household size is declining slightly and currently lies at around two persons per household.

In private households a good 43 mio. cars were available in 2017, with a recorded overall number of around 46 mio. of such vehicles which are, however, not all available in private households. The fleet figures have continued to increase in recent years. In 2002 and 2008 the privately available fleet of cars stood at just below the number of recorded households. In 2017 it lay over this number and on average more than one privately available car is related to every household. Nevertheless, similarly to in 2008, a good one in five households does not own a car.

As the diagram shows, the ownership of more than one car increases slightly as time progresses. In 2017, despite the increasing number of households, every fourth household owns two or more cars. This car ownership level depends to a large extent on a household's residential region. In the metropoles for example, four in ten households have no car. Hamburg and Munich are, for instance, included in this category. In contrast, in the most rural regions, at least one car per household continues to be considered a basic provision. In such areas more than 90 per cent of households have a minimum of one car at their disposal. Almost 40 per cent even have access to two or more cars. The growths to be ascertained in the overall number do not always turn out the same. While the results of number of cars in private households are different according to federal states, growth in the four sparsely populated eastern German states particularly stands out. The backlog in demand in these areas was apparently not satisfied in both 2002 and 2008. In particular the size of the group of households with one available car has aligned with the rest of the country.

Around 75 mio. (electric) bicycles

The number of available bicycles is also determined by Mobility in Germany. Since 2017 it is possible to differentiate between 'conventional' and electric bicycles. Only in every fifth household in 2017 is there no 'functioning' bicycle. 78 per cent of the households therefore have at least one roadworthy bicycle to call their own. In eight per cent of households this even includes at least one electric bicycle. Similarly to 2002 and 2008, almost four in five interviewed persons stated that they have at least one bicycle at their disposal. When extrapolated, this results in an overall fleet of around 75 mio. bicycles, more than 4 mio. of which are electrically supported. The overall fleet number has grown by over 5 mio. since 2002.

Access to public transport

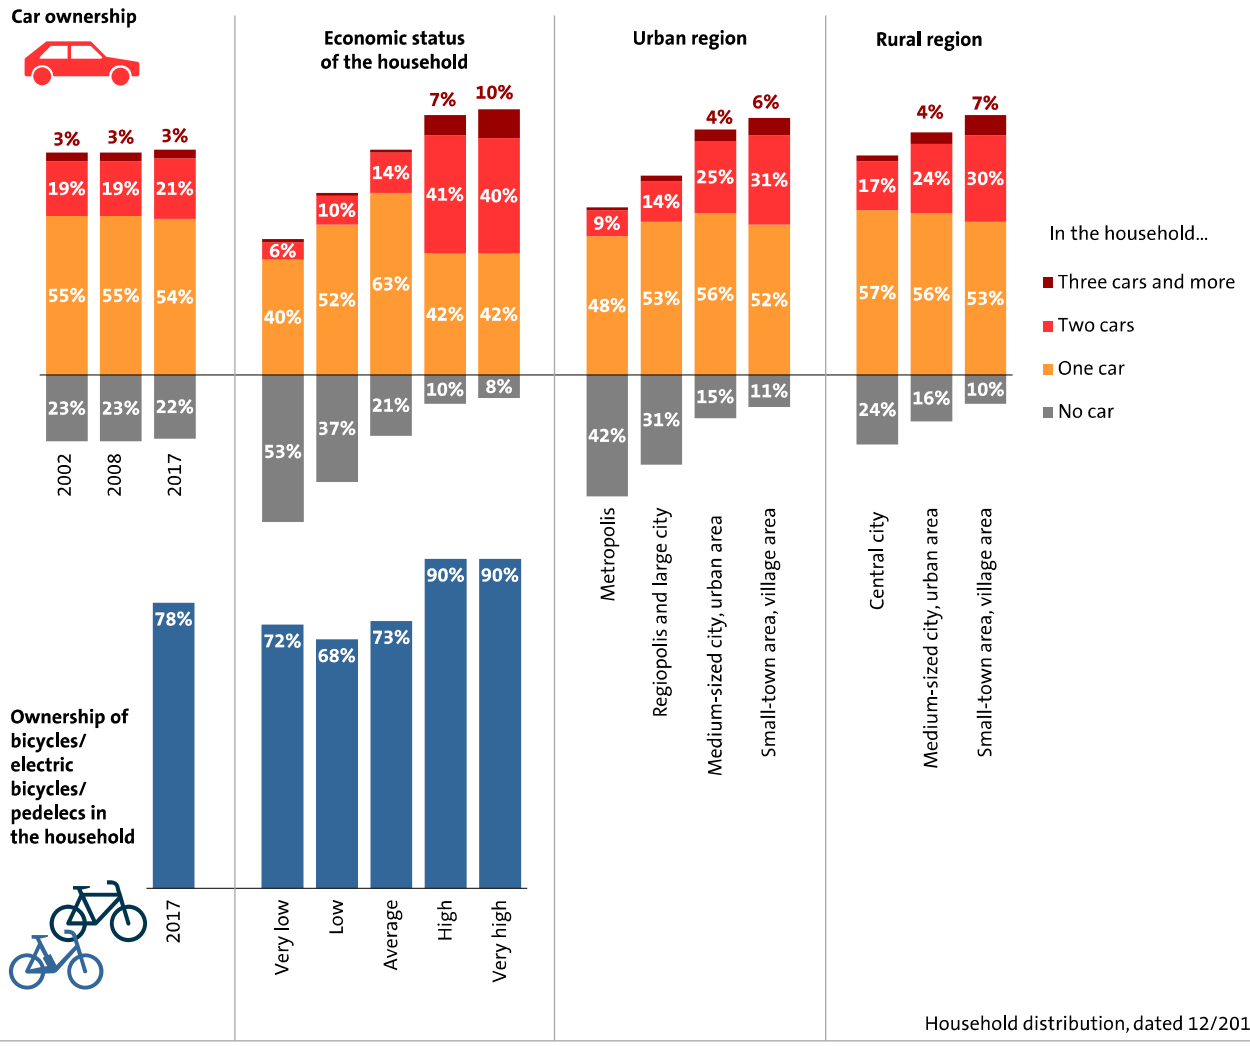

Unlike with the bicycle and car, the approach of Mobility in Germany 2017 is different to that in 2002/2008 when it comes to public transport. Ongoing spatial analyses will, in further reports, offer the possibility of classifying the surveyed households according to the objective quality of connection to the place of residence. All persons aged 14 and over were asked about the transport tickets they normally use. 26 per cent of them stated that they did not make use of buses or rail transport. A further 52 per cent usually decide on a single or stripe (multiple single) ticket. The remaining 22 per cent carry some kind of season ticket with them. They therefore have easier access to local public transport, at least in terms of the hurdle of obtaining a ticket. Compared to 2008 the number of non-users has dropped somewhat and the share of season ticket owners has grown somewhat.

Going by foot is important

The following chapter looks at the specific proportion of public transport in the travelled trips, as well as the trips managed purely on foot. Walking is often a very underestimated mobility option. Even though this proportion is sinking, every fifth trip is still being covered on foot alone. 33 per cent of the interviewees aged 14 and over stated that they very much enjoyed walking, 41 per cent cover individual distances every day on foot alone.

Which modes of transport do we use?

Modal split as important indicator – slight plus for public transport and the bicycle, no decline in car transport

One of the most important key values for Mobility in Germany is the so-called 'modal split'. It expresses the proportional share of the modes of transport over the entire transport volume and thus over all trips covered. As in the years 2002 and 2008, almost 60 per cent of the nationwide average is related to private motorised transport. This includes the use of a car, but also 25 km/h and 45 km/h mopeds and motorcycles as well as utility vehicles. In the 2017 survey the use of car sharing is also included (for details on this, see the separate section in this short report). 43 per cent were private motorised vehicle drivers and 14 per cent were passengers. In this examination, slight growth is recorded by the bicycle and public transport (in Mobility in Germany, public transport is defined as including long-distance transport and taxis, whereby the by far largest proportion within public transport is related to local passenger transport). The proportion of bicycles rose from 9 per cent in the year 2002 to almost 11 per cent in the year 2008 and a good 11 per cent in the year 2017. The proportion of public transport grew from 9 to now 10 per cent. The proportion of trips covered on foot alone declined slightly from 24 and 25 per cent in the first two surveys in 2002 and 2008 to currently 22 per cent.

These modal shares can be examined not only in terms of the trips covered, but also for the passenger kilometre performance. As the average distances between the two modes of transport vary considerably, a very different distribution results from this perspective. Thus, in 2017, drivers in private motorised transport account for 55 per cent and passengers in private motorised transport account for 20 per cent of all passenger kilometres. This means that private motorised transport accounts for over three quarters of all passenger kilometres. Therefore, over three quarters of all passenger kilometres are managed together with private transport. At second place is public transport with almost a fifth, followed by the bicycle with 4 per cent, and trips on foot still at a respectable kilometre share of 3 per cent.

Absolute values as important benchmark

This proportional examination can be extended by analysing the extrapolated absolute values. Due to the fact that the number of trips per person and day have reduced overall – as has already been demonstrated – and the average distances have also changed somewhat, this presents an important addition, in particular on a kilometre level. Of the measured daily transport distance of overall around 3,200 mio. passenger kilometres, around 2,400 mio. are related to private motorised transport. This lies slightly over the range of 2008 and significantly over the level of 2002. If only the car drivers are examined here – i.e. the vehicle movements – the car vehicle mileage continuously increases from 2002 to 2017.

This result of a rising absolute transport distance applies to the bicycle to a much more significant extent. Its values have increased from 96 mio. daily 'pedalled' kilometres in the year 2008 to a current 112 mio. This increase comes about from the twofold effect of a somewhat higher trip share in the decimal figure and, in 2017, an on average somewhat longer individual distance of trips ridden on the bicycle – also displayed in the accompanying summary on the following page.

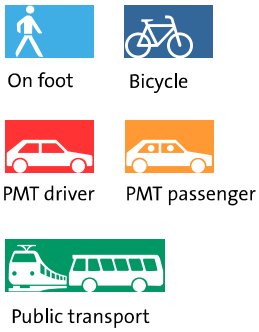

Modal split in the federal states with significant differences

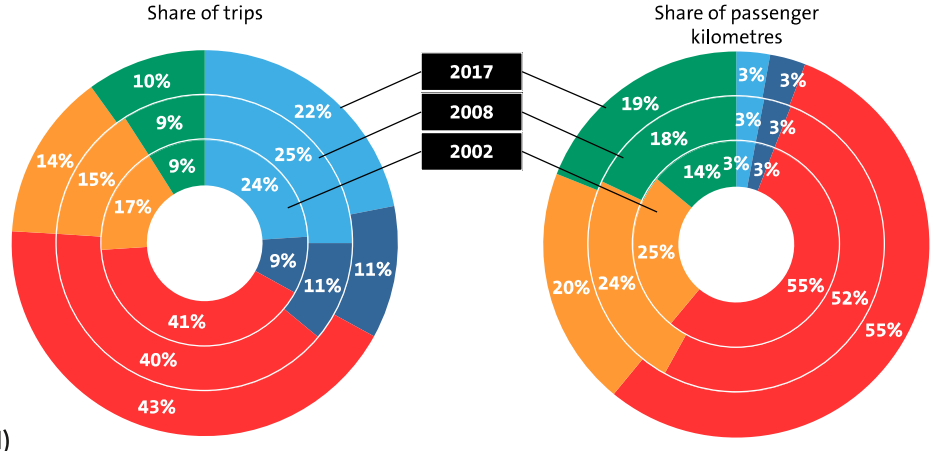

All things considered however, the reported changes turn out to be only relatively low despite a recognisable trend towards the bicycle and public transport. The car remains by far the number one mode of transport. This relativisation particularly applies against the backdrop of the almost decade long time span from 2008 to 2017.

All the more important then, is the differentiated look at the individual results for the federal states as well as the differentiation according to the spatial types applied by Mobility in Germany. The two modal split results displayed on the right show clear differences between urban and rural regions as well as their further differentiations. In particular the city states of Hamburg, Bremen and Berlin show higher proportions of bicycle and public transport. It is a similar picture for the accompanying category of metropoles. In this case – as the extensive Mobility in Germany reporting shows in detail at a different point – in particular the proportion of public transport but also the proportion of bicycles has risen more intensely than the national average.

Trips

Modal split

Modal split (extrapolated)

	Trips *in mio. per day*			Passenger kilometres *in mio. per day*			Trip lengths *in km 2017*	
	2002	2008	2017	2002	2008	2017	*Average value*	*Median**
On foot	64	69	**56**	88	98	**93**	1.7	1.0

*This value represents the average of each available distribution and assists in allocating an average value which is often influenced by high individual values. Legend, trip length for trips on foot: The median lies at 1.0 km. Therefore, 50 per cent of the reported trips on foot are up to a distance of 1.0 km and 50 per cent exceed this value. Columns 2017: Data inventory 12/2018

How are different user segments distributed?

Usual day-to-day use of transport modes and in longer holiday transport

In addition to the results on transport volume and the transport distance, Mobility in Germany also enables an examination of the usual modes of transport since 2002. For this purpose, all persons aged 14 and over were asked about their usual utilisation of different transport services. Since 2017 this also includes long-distance buses and trips taken on foot alone. Likewise, questions were also asked in the same way about the use of car sharing as well as cycling using a rental bicycle. These replies enable conclusions to be drawn on the general pattern of use, unlike the details provided on the use of modes of transport on a randomly selected survey date. When combined, they additionally enable an informative segmentation.

In a time comparison, the information provided in 2017 leads to a slightly declining usual use of the car while the utilisation of the bicycle and public transport is rising. The share of persons who regularly take seat in a car is reduced in 2017 compared to the other two reporting times from over four fifths to around three quarters of the interviewees at the age of 14. On the other hand, in terms of travelling by bus or rail or on a bicycle, it is rather the proportion of those who never or only rarely entrust themselves onto public transport or swing their legs over a bicycle which has declined. Both modes of transport therefore are gaining users who at least occasionally travel in this way. This is true of the bicycle to a particular extent.

The 'new' modes of transport are still at a low level. Two per cent of the included interviewees who are aged 14 and over are to be counted among the at least sporadically regular car sharing users here – not to be confused with car sharing members, more about this in the next section. This group is somewhat larger when related to a shared bicycle. It even reaches a size of 4 per cent – whereby the questions here asked specifically about every-day use and not leisure use, for example on holiday. An option which is by no means new but is often underestimated is that of going by foot. Here the results show that four in ten citizens completely cover at least individual trips daily or almost daily on the soles of their feet alone.

The two depicted forms of long-distance transport also lead to different user quotas. In long-distance transport by rail from a distance of 100 kilometres results in a non-user proportion of around six in ten interviewees. In long-distance buses this lies at nine in ten and by aeroplane at seven in ten persons.

High car-orientation away from the towns is the rule

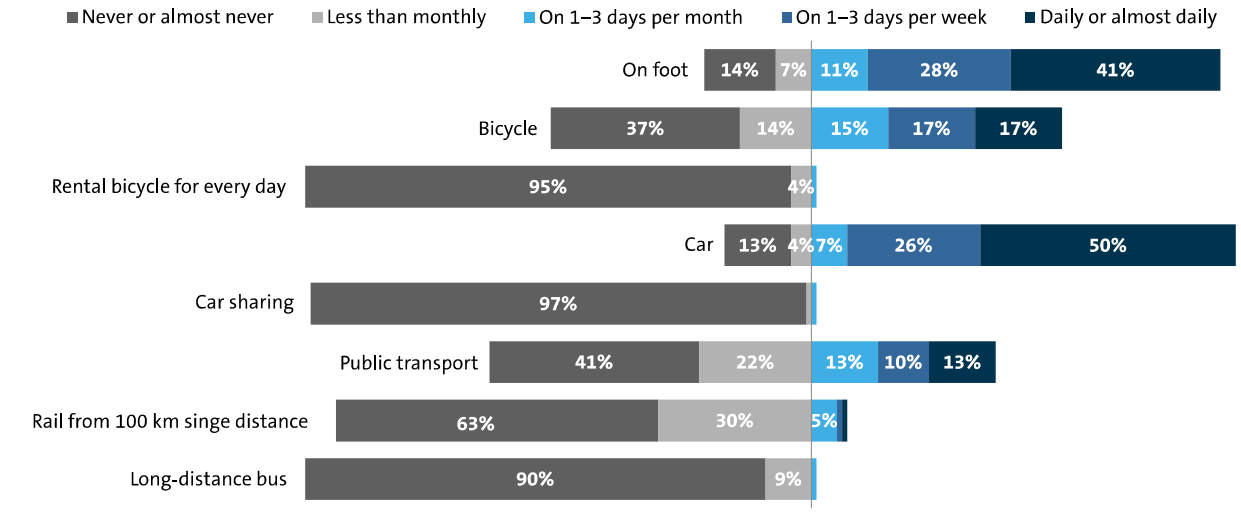

The details on the individual modes of transport can be considered in relation to each other. Based on every-day and occasional uses, nine groups were formed and displayed in the graphics. These range from the less mobile who hardly travel at all during the course of the week to those who travel almost solely by car every day and almost never make use of other services. Likewise, an examination of the 'regular multiple users' is possible, here with the definition that they go by car, public transport and also bicycle as a rule at least once during the course of the week.

An examination over time from 2002, 2008 and 2017 shows an unchanged share of multiple users of 7 to 8 per cent. It's a different picture for the 'daily car-orientated'. They continue to represent the largest group. Their share rose slightly in 2017 and reached 44 per cent. On the other hand, similarly to the share of bicycle-orientated, the size of the segment of public transport users has hardly changed. The share of 'mixed users with car driving licence' has declined slightly in the nationwide average. Here, in particular persons can be found who use both the car as well as public transport or the bicycle, in contrast to the 'multiple user' however they do not regularly use all three services.

The undertaken subdivision enables further differentiations, for example according to urban or more rural situations as depicted here. Likewise, the socio-demographic profile of the segments can also be examined. The in-depth Mobility in Germany report presents more specific analyses on this.

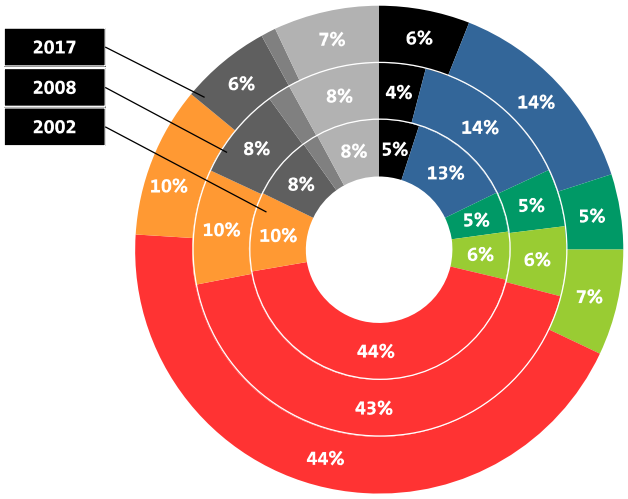

Persons aged 14 and over

Frequency of the usual use of transport modes

Discrepancies of 100%: Rounding differences

Mobility segments according to usual use of transport modes

Columns-%, rounding-related discrepancies of '100' possible

			Urban region				Rural region		
			Metropolis	Regiopolis and large city	Medium-sized city, urban area	Small-town area, village area	Central city	Medium-sized city, urban area	Small-town area, village area
	Less mobile	Use no mode of transport at least weekly	6%	6%	5%	4%	7%	6%	5%
	Bicycle-orientated	Use the bicycle daily or weekly and all other modes of transport more rarely	18%	17%	12%	9%	18%	12%	9%
	PT-orientated without car driving licence	Use public transport daily or weekly, other services more rarely and do not have a car driving licence	10%	7%	3%	2%	4%	2%	2%
	PT-orientated with car driving licence	Use public transport daily or weekly, other services more rarely and have a car driving licence	19%	11%	5%	3%	5%	2%	1%
	Daily car-orientated	Use the car daily or weekly, other services more rarely	26%	37%	50%	58%	43%	53%	59%
	More rarely car-orientated	Use the car more rarely than weekly, other services also rarely	5%	8%	11%	11%	10%	12%	13%
	Mixed users with car driving licence	Use different modes of transport daily or weekly, have a car driving licence	6%	5%	7%	6%	5%	5%	5%
	Mixed users without car driving licence	Use different modes of transport daily or weekly, without a car driving licence	1%	1%	1%	1%	1%	1%	1%
	Regular multiple users	Use *both* car *as well as* bicycle *and* public transport at least weekly	8%	7%	7%	6%	7%	6%	6%
